In account of the Arachnides of the United States.
By Thomas Say.

The following descriptions of the Arachnides of this country, which respire by means of trachea in the manner of insects, may be regarded as the continuation of a series of essays, of which the "account of the Crustacea," \&c. is the first, on the vast orders of articulated animals with articulated feet, (Annulosa of.Cuvier) natives of this country. As the nature of the journal precludes the introduction of old matter or known facts, I shall confine myself in its pages, to the description of such of these animals only, as appear to be unknown to naturalists, or to the elucidation of such, as from their obscurity, are not understood.

## subclass I CEPHALOSTOMATA.

order 1st, PODOSOMATA.
genus *ANAPHIA. $\dagger$

1'l. 5. fig. 7.- $a$ Trophi.

Artificial Character.-Mandibles longer than the rostrum, first joint longer than the second; palpi none ; nails single.

Natural Character.-Body very slender, composed of four segments bearing feet, and a small suboval caudal process; head prominent, not perceptibly contracted behind, and consisting of a prolongation of the anterior segment of the body; eyes four,

[^0]inserted on a common tubercle, upon the top of the head : maindibles rohust, didactyle, inserted at the extremity of the head, porected, parallel, two-jointed, longer than the rostrum, first joint elongated attaining the tip of thestrum ; hand abruptly inflected upon the tip of the rostrum ; rostrum porected. cylindrical, trincated at tip, shorter than the hody, and inserted beneath the first segment; palpi none ; feet eight, filiform elongated, slender; coxse three jointed, the middle one longest ; thighs one-jointed; tibice two-jointed; tarsi two-jointed, the first very short; nails single, arcuated, capable of being inflected.

Species.-A. *pallida. Body whitish ; ocular tubercle acute at tip; eyes sanguineous: hands suboval, slightly hairy, not dilated, inflected vertically, and with the fingers, hardly more than two-thirds the length of the preceding joint; fingers arcuated, crosssing each other near the tip; a small, rather acute tubercle at the base of the anterior feet (probably the rudiment of the egg-bearing organ;) coxce second joint clavate ; tibice first joint rather shorter than the second.
length of the body 1-4 of an inch.
Span of the feet 1 1-2 inch.
Inhabits the coast of South Carolina.
Cabinet of the Academy.
Of this new genus I found two specimens in the bay of Charleston, S. C. upon the branches of the Gorgonia virgulata, and as they have not the eggbearing organs, I suppose them to be males. This
animal resembles Phoxichilus in being destitute of palpi, but differs from it in having didactyle mandibles and simple nails. In the form of the mandibles it resembles Nymphon and Ammothœea but the want of palpi distinguishes it from those genera, its proper situation is probably next to the genus Phoxichilus. It, unquestionably, is generically the same with Phalangium aculeatum of Montague, (Trans. Lin. Soc. vol. 9, tab. 5,) which Dr. Leach, in the article Crustaceology of Brewster's Encyclopædia, refers to the genus $\boldsymbol{N} y m p h o n$, but which, as far as I can discover, he has omitted in his subsequent works. It will of course be a second species of this new genus.

## order II. POLYMEROSOMATA.

## family 2. SCORPIONIDEE.

Genus BUTHUS. Leach. Scorpio, Latr.
Palpi brachiform, didactyle ; eyes eight ; abdomen terminated by a caudal process of six articulations, of which the terminal one is armed with a venomous aculeus.

Species.-B. *vittatus. Fuscous, with three fulvous vitta; sides black.

Inhabits Georgia and Florida.
Cabinet of the Academy.
Body above granulated, granules irregalar, distant, three fulvous equal vitta, and an elevated, interrupted vertebral line; sides black, rugose, beneath white; thorax reddish brown, more scabrous before and be-
hind, hardly marked by the vitta, subemarginate before, and divided by a longitudinal impressed line, region of the dorsal eyes blackish ; palpi longer than the body, with granulated lines, carpus with three or four of the granules more conspicuous: hand subovate, greatest diameter about equal to that of the preceding joint; fingers filiform, incurved, longer than the hand, reddish-brown, furnished with numereus minute teeth; feet paler than the palpi, minutely granulated above and beneath; caudal process colour of the palpi, longer than the body, with granulated costa, those of the penulimate segment not more conspicuous; terminal segment subovate, slightly mucronate beneath the aculeus, the costal granula minute.

Length from tip of the palpi to tip of the caudal process, 1 inch and 7 -10ths.

I found numerous specimens of this species on the sea islands of Georgia and in East Florida, hybernating beneath the bark of trees.

The wouad inflicted by the puncture of their aculeus, causes much pain and intumescence, but is readily cured by the topical application of the volatile alkali.

The species to which vittatus is allied, are the punctatus of Degeer and Americanus of Linné, but according to Latrielle (v. Sonninis' Buffon) these are both spotted with brown, the caudal process of punctatus being of the length of the body and that of Americanus three times the length of the body.

It is, however, very possible that our species may be a variety of punctatus.

Genus CHELIFER. Geoff, Leach.
Palpi hrachiform, didactyle ; thorax with the first segunent dtvided by a transverse indented line; eyes two; mandibles short.

Species.-1. C. *muricatus. Third joint of the palpi nearly three times as long as the second, linear, gradually a little attenuated to the base ; thorax muricated.

Inhabits North America.
Cabinet of the Academy.
Body ovate, narrowed before, rounded behind; thorax black brown opake, gradually narrowed from the base to the tip of the nandibles, armed with numerous short, robust spines; feet rufo-testaceous; palpi rufous, basal joints subglobular, gibbous behind, third joint cylindrical, nearly three times longer than the second, armed with short rigid hairs, and gradually attenuated to the base, fourth joint shorter but somewhat larger than the preceding one, and gradually much attenuated to its base ; hand black-brown, above oblong-subovate, laterally linear, fingers as long as he hand, paler, incurved and furnished with a few elongated, flexible hairs ; abdomen above black-brown, and with the feet furnished with minute, spinelike hairs, segments margined with obsolete pale testaceous.

Length rather more than 1-10th of an inch.

Common in decaying wood, under bark, in houses, under stones, \&c. I found a variety on the river St. John, in East Florida, of which the anterior portion of the abdomen and posterior part of the thsrax is rufous. This species considerably resembles $\mathbf{C}$. Hermanni of Leach, (Zool. Misc. vol. 3, p. 49.)
2. C. *oblongus. Second joint of the anterior feet hardly twice as long as the first, rather larger towards the base ; thorax polished.

Inhabits North America.
Cabinet of the Academy.
Body oblong, sublinear ; thorax reddish brown, polished, testaceous at base, rather abruptly attenuated from the middle to the tip, and with abbreviated flexible lairs, instead of spinules ; feet pale, testaceous; palpi reddish-brown, with dilated, short joints, and furnished with numerous flexible hairs, second and third joints subequal, the latter rather shorter and dilated in the middle; hands ovate, almost truncated at base; fingers shorter than the hand, and with a few longer hairs; abdomen above brownish, slightly hairy, polished, margins of the incisures testaceous. Smaller than the last.

Occupies the same situations as the preceding. It bears considerable resemblance, in the form of the palpi, to the C. Geoffroyi of Leach, (Zool. Misc. p. 50.) This species, as well as the preceding, are readily distinguishable from the Phalangium acaroides of Linne, by the mutic antepenultimate segment of the palpi.
order 3. DUOMEROSOMATA.

## family 2. PHALANGIDEE.

## genus PHALANGIUM.

Body rounded; feet elongated; tarsi with numerous joints; mandibles salient much shorter than the body: eyes two, supported on a common tubercle.

Species. 1 P. *vittalum. Whitish, with a dorsal fuscous vitta ; terminal joint of the palpi not pectinated with spines.

Inhabits the Southern States.
Cabinet of the Academy.
Body whitish, truncated and fuscous behind, a dorsal fuscous vitta from the clypeus to the cloaca and lateral fuscous line, above with dense, obtuse granules, beneath with distant ones; three profoundly impressed lines before the middle, of which the anterior one is semicircular including the ocular tubercle, the intermediate one transverse, and the posterior one recurved; ocular tubercle prominent, slightly contracted at base, crowned with from four to six more conspicuous, acute spines; clypeus not elevated, concave beneath the obtuse tip; feet, second pair about fifteen times as long as the body; tarsi capillary, articulations not contracted.
Length, female nearly one-fifth of an inch. Male much smaller.

The armature of the ocular tubercle is obsolete in the male, and in this sex there are generally two

[^0]:    $\dagger$ From $\alpha$, without, and $\alpha \varphi_{i}$, tactus the touch.
